ABSTRACT

This project presents an automatic fan speed control system that adjusts fan operation according to surrounding temperature using embedded system technology. The system consists of a temperature sensor, microcontroller, and Pulse Width Modulation (PWM) circuit. The sensor continuously measures ambient temperature and sends the data to the microcontroller, which automatically regulates fan speed based on predefined temperature levels. Fan speed increases with rising temperature and decreases when the temperature falls, reducing unnecessary energy consumption. Performance testing demonstrated effective temperature-based cooling, improved user comfort, and energy efficiency. The proposed system is economical, easy to implement, and suitable for homes, offices, laboratories, and industrial applications.

1. INTRODUCTION

The increasing demand for electricity in homes and industries has created a strong need for smart technologies that can improve energy efficiency while maintaining user comfort. Electric fans are among the most frequently used household appliances, particularly in regions with warm climates where they operate for long hours each day. Most conventional fans require users to adjust the speed manually, making them unable to respond to changes in room temperature. As a result, they may consume more electrical power than necessary and provide inconsistent cooling performance.

Recent developments in embedded system technology have enabled the design of intelligent appliances that can monitor environmental conditions and automatically adjust their operation. Modern microcontrollers, combined with accurate temperature sensors and efficient motor control techniques, provide a practical and economical solution for implementing automated control systems. These

technologies support real-time data processing and precise control, making them suitable for energy-saving applications.

A temperature-based fan speed control system offers an effective method for improving both comfort and power efficiency. By continuously measuring the surrounding temperature, the system can automatically regulate the fan speed according to current cooling requirements. Pulse Width Modulation (PWM) is used to vary the motor speed smoothly, ensuring efficient operation without unnecessary energy consumption. This approach reduces the need for manual adjustments, improves overall system performance, and supports sustainable energy management. The proposed study focuses on designing and implementing such an embedded control system to demonstrate its effectiveness in providing intelligent and energy-efficient cooling.

2. SYSTEM ARCHITECTURE AND DESIGN METHODOLOGY

The proposed system is divided into three main modules: the sensing module, the processing module, and the output module. Together, these modules enable continuous temperature monitoring, intelligent decision-making, and automatic fan speed adjustment.

The sensing module uses a temperature sensor, such as the LM35 or DHT11, to measure the surrounding air temperature. Depending on the selected sensor, the measured temperature is provided as either an analogue or digital signal. The sensor is placed in a suitable location to obtain accurate environmental readings while minimizing the influence of external disturbances. These temperature readings are then sent to the microcontroller for further analysis.

The processing module is based on a microcontroller platform, such as an Arduino or PIC controller, which functions as the core of the system. It continuously receives temperature data from the sensor, compares the measured values with predefined temperature ranges, and determines the required fan speed using a programmed control algorithm. To achieve smooth and efficient speed regulation, the microcontroller generates Pulse Width Modulation (PWM) signals that adjust the power delivered to the fan motor (Patel & Mehta, 2024).

The output module includes a motor driver circuit and the DC fan. The driver circuit, commonly implemented with a transistor or MOSFET, strengthens the PWM control signal so that it can safely operate the fan motor. This configuration provides reliable speed control, efficient power delivery, and stable system performance under different operating conditions.

3. WORKING PRINCIPLE AND CONTROL STRATEGY

The operational principle of the system is based on continuous feedback and proportional control. The temperature sensor measures ambient conditions and sends real-time data to the microcontroller. The controller processes this data using a predefined algorithm that maps temperature ranges to corresponding PWM duty cycles.

At lower temperatures, the PWM duty cycle remains minimal, resulting in reduced fan speed. As the temperature increases, the duty cycle is proportionally increased, causing the fan to rotate faster. This dynamic adjustment ensures that the cooling effect matches the thermal requirement, thereby enhancing both efficiency and comfort (Rao et al., 2022).

The control strategy can be implemented using simple threshold-based logic or more advanced proportional-integral (PI) control methods. While threshold-based control is easier to implement, PI control provides smoother transitions and improved stability.

Table 1: Temperature vs PWM Duty Cycle Mapping

Temperature Range (°C)	PWM Duty Cycle (%)	Fan Speed Level
< 25	20	Low
25 – 30	40	Medium
30 – 35	70	High
> 35	100	Maximum

This mapping ensures that the system responds effectively across a wide range of environmental conditions.

4. HARDWARE IMPLEMENTATION AND EXPERIMENTAL SETUP

The hardware implementation involves assembling the sensor, microcontroller, driver circuit, and fan motor into a cohesive system. The temperature sensor is interfaced with the

analogue input of the microcontroller, while the PWM output pin is connected to the gate of a MOSFET driver circuit. The fan motor is powered through this driver, allowing precise control over its speed.

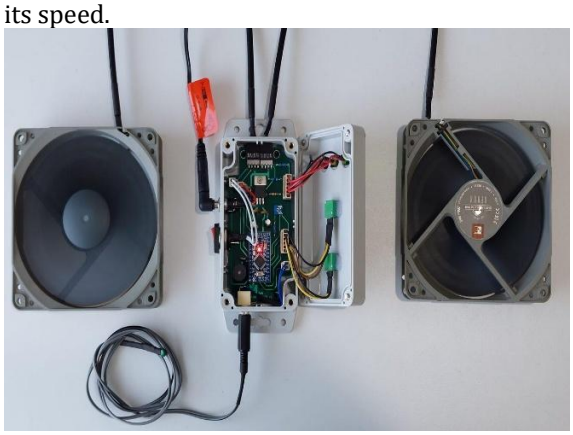

Figure 2: Experimental Setup of Embedded Fan Control System

The system was tested under controlled laboratory conditions with varying temperature inputs. A heat source was used to simulate temperature changes, and the corresponding fan speed was measured using a tachometer. Power consumption was monitored using a digital power meter to evaluate energy efficiency.

Table 2: Experimental Results of System Performance

Temperature (°C)	Fan Speed (RPM)	Power Consumption (W)
24	500	15
28	900	25
32	1300	40
36	1800	60

The results indicate a clear relationship between temperature and fan speed, validating the effectiveness of the control mechanism.

5. RESULTS AND DISCUSSION

The experimental findings confirm that the proposed system successfully achieves adaptive control of fan speed based on ambient temperature. Compared to conventional fixed-speed operation, the system demonstrates significant energy savings, particularly during moderate temperature conditions where full-speed operation is unnecessary.

The use of PWM control enables fine-grained speed regulation, minimizing abrupt changes and enhancing system stability. Additionally, the embedded control approach ensures rapid response to temperature variations, maintaining a consistent comfort level for users.

From an economic perspective, the system is highly feasible due to the low cost of components and ease of implementation. The scalability of the design further allows integration with advanced smart home systems and IoT platforms, enabling remote monitoring and control (Verma & Joshi, 2023).

However, certain limitations must be acknowledged. Sensor accuracy and calibration play a critical role in system performance. Environmental factors such as humidity and airflow patterns may also influence temperature readings. Future research may focus on integrating multiple sensors and advanced control algorithms to enhance robustness and reliability.

6. CONCLUSION

This study presents a comprehensive approach to designing an automatic temperature-based fan speed control system using embedded control techniques. By integrating real-time sensing, intelligent processing, and efficient actuation, the system addresses key challenges associated with conventional fan operation, including energy inefficiency and lack of adaptability.

The results demonstrate that the proposed system not only improves energy utilization but also enhances user comfort through responsive environmental control. Its simplicity, affordability, and scalability make it a viable solution for widespread adoption in both residential and industrial contexts.

The broader implication of this work lies in its contribution to the development of smart and sustainable technologies. As embedded systems continue to evolve, their application in everyday appliances will play a crucial role in shaping energy-efficient and intelligent living environments.
