ABSTRACT

Women's safety has become a major concern due to the increasing number of crimes, harassment cases, and unsafe public environments. Although several safety applications are available, most provide only basic emergency services such as SOS alerts and location sharing, without intelligent risk analysis or predictive assistance. This paper presents the Smart Women Safety System, an AI-powered web application designed to enhance women's safety through real-time monitoring and intelligent decision-making. The proposed system integrates Machine Learning, Flask, SQLite, OpenStreetMap, and browser-based technologies to analyze the user's live location and estimate the safety level of the surrounding area. Based on factors such as crime-prone locations, nearby emergency services, and environmental conditions, the system classifies the location as Safe, Medium Risk, or High Risk, and generates an AI Safety Score with personalized recommendations.

1. INTRODUCTION

Women's safety has become one of the most significant social concerns in today's world due to the increasing number of crimes, harassment, and security threats in both urban and rural areas. Although various safety applications have been developed to provide emergency assistance, many of them are limited to basic functionalities such as sending SOS alerts or sharing live locations. These conventional systems often lack intelligent decision-making capabilities, real-time risk analysis, and proactive safety recommendations, reducing their effectiveness during critical situations.

With the rapid advancement of Artificial Intelligence (AI), Machine Learning (ML), and Location-Based Services (LBS), it has become possible to develop smart applications that not only respond to emergencies but also predict potential risks before they occur. By analyzing real-time location data, crime statistics, and nearby emergency facilities, AI-powered systems can provide users with valuable insights regarding their safety and recommend appropriate preventive actions. Such intelligent systems can

significantly enhance personal security by enabling users to make informed decisions while traveling or visiting unfamiliar locations.

The Smart Women Safety System is a web-based application developed to improve women's safety through intelligent monitoring and real-time assistance. The system combines Machine Learning algorithms, Flask web framework, SQLite database, and OpenStreetMap to provide a comprehensive safety platform. It evaluates the user's current location, predicts the surrounding safety level, and categorizes the area into Safe, Medium Risk, or High Risk. Based on the predicted risk level, the application generates an AI Safety Score and provides personalized safety recommendations.

In addition to AI-based risk prediction, the system incorporates several essential safety features, including live location tracking, safe route recommendation, emergency SOS alerts, Voice SOS activation, nearby police station and hospital locator, trusted contact management, AI Safety Assistant, and safety analytics dashboard. The proposed system aims to bridge the gap between traditional emergency applications and intelligent safety solutions.

2. RELATED WORK

Several research studies and existing applications have been developed to improve women's safety using mobile technologies, GPS tracking, and emergency alert systems. Most conventional safety applications primarily focus on sending emergency messages and sharing the user's live location with predefined contacts during critical situations. While these systems provide immediate assistance, they often lack intelligent risk prediction and proactive safety analysis.

Recent research has explored the use of Internet of Things (IoT), wearable devices, Artificial Intelligence (AI), and Machine Learning (ML) to enhance women's safety. AI-based approaches utilize historical crime data, location information, and environmental factors to predict unsafe areas and provide preventive alerts. Machine learning algorithms have demonstrated promising results in identifying high-risk locations and assisting users in making safer travel decisions. However, many existing systems are limited by the availability of real-time data, high implementation costs, or dependence on dedicated hardware devices.

Web-based safety platforms have gained popularity due to their accessibility and ease of deployment. Technologies such as Flask, OpenStreetMap, and browser-based Geolocation APIs enable developers to build lightweight and scalable applications without requiring additional hardware. The proposed Smart Women Safety System addresses these limitations by integrating Machine Learning with real-time location services to provide intelligent safety prediction and emergency support within a single web application.

3. PROBLEM STATEMENT

Women frequently encounter safety challenges while traveling, working late hours, or visiting unfamiliar locations. Existing safety applications generally provide only reactive solutions such as emergency SOS alerts or location sharing after a dangerous situation has already occurred. These systems lack intelligent mechanisms for assessing environmental risks, predicting unsafe areas, and recommending preventive actions before an emergency arises.

The absence of real-time safety prediction and personalized assistance limits the effectiveness of traditional safety applications. Users often remain unaware of nearby crime-prone areas, available emergency facilities, or safer travel routes. Furthermore, many existing systems do not integrate multiple safety services into a unified platform, resulting in fragmented user experiences and delayed emergency responses. Therefore, there is a need for an intelligent, web-based women safety platform that utilizes Artificial Intelligence, Machine Learning, and real-time location analysis to predict safety levels and offer comprehensive emergency support.

4. PROPOSED SYSTEM ARCHITECTURE

The architecture of the proposed Smart Women Safety System is designed in a modular manner to ensure efficiency, reliability, scalability, and real-time safety monitoring. The system consists of five major components: the Frontend Module, Application Server, AI Module, Database, and Maps & Location Integration.

A. Frontend Module

The frontend serves as the user interaction layer of the system and provides a simple, responsive, and user-friendly interface. Users can register, log in, and access various safety features through an intuitive dashboard. The frontend allows users to view their live location, check the AI Safety Score, receive personalized safety recommendations, activate SOS and Voice SOS features, manage trusted contacts, and locate nearby police stations and hospitals. The interface is developed using HTML, CSS, JavaScript, and Leaflet.js.

B. Application Server

The application server acts as the core processing unit of the system and is developed using the Flask framework. It handles all client requests received from the frontend, performs user authentication, manages user sessions, validates input data, and coordinates communication between different modules. The backend also interacts with the SQLite database to store and retrieve user

information, prediction history, and emergency contact details.

C. AI Module

The Artificial Intelligence module forms the intelligent component of the proposed system. It utilizes a Random Forest Machine Learning algorithm trained on crime-related and location-based data to predict the safety level of the user's current location. Based on the analyzed parameters, the model classifies the area into Safe, Medium Risk, or High Risk categories. The AI module also generates an AI Safety Score and provides personalized recommendations.

D. Database Module

The database is responsible for securely storing and managing all application data. SQLite is used as the relational database management system due to its lightweight nature and efficient performance. The database maintains records of registered users, login credentials, trusted contacts, prediction history, safety reports, and other application-related information.

5. SYSTEM DESIGN AND METHODOLOGY

A. User Registration, Authentication, and Location Processing

The operation of the Smart Women Safety System begins with user registration and secure authentication through the web interface. Users create an account by providing basic details, after which their credentials are securely stored in the SQLite database. Once authenticated, the application requests permission to access the user's current location using the browser's Geolocation API. The obtained latitude and longitude coordinates are validated and processed to ensure accurate location tracking.

B. AI-Based Safety Prediction and Risk Analysis

The core functionality of the proposed system is driven by an Artificial Intelligence module based on the Random Forest Machine Learning algorithm. The processed location data, along with predefined safety-related parameters, is provided as input to the trained model. The AI module analyzes the surrounding conditions and predicts the safety level of the user's current location by classifying it into Safe, Medium Risk, or High Risk categories. Based on the prediction, the system generates an AI Safety Score.

C. Emergency Assistance, Safe Route, and Support Services

Following the safety prediction, the application provides multiple emergency assistance features to support users during critical situations. The system integrates OpenStreetMap and Leaflet.js to display the user's live location and identify nearby police stations, hospitals, and other emergency facilities. A safe route recommendation feature assists users in selecting comparatively secure paths while avoiding high-risk areas. Users can activate SOS or Voice SOS features to seek immediate assistance.

D. Safety Analytics and System Optimization

The Smart Women Safety System continuously records user activities, prediction history, and safety assessments to improve system performance and provide meaningful insights. The collected data is stored securely in the SQLite database and presented through an interactive analytics dashboard using graphical visualizations. These analytics help users monitor safety trends and review previous risk patterns.

6. IMPLEMENTATION

A. Technology Stack

The proposed Smart Women Safety System is implemented using a combination of web development, machine learning, and location-based technologies to ensure efficiency, scalability, and real-time performance. The frontend is developed using HTML, CSS, JavaScript, and Leaflet.js integrated with OpenStreetMap. The backend is developed using Python with Flask. Machine learning relies on Scikit-learn, Pandas, NumPy, and Joblib, while SQLite handles database management. System visualization is built with Chart.js.

B. Data Management and Safety Monitoring

A structured database management system is implemented using SQLite to maintain user registration details, login credentials, trusted contacts, prediction history, and safety reports. During execution, the Geolocation API continuously retrieves live location coordinates, which are supplied to the Machine Learning model to calculate safety scores and identify nearby support services.

C. AI Model Implementation

The Artificial Intelligence module uses the Random Forest Machine Learning algorithm. The model is trained using a crime-related dataset containing safety parameters that assist in classifying locations into Safe, Medium Risk, and High Risk categories. Preprocessing steps include data cleaning, feature selection, and normalization to maximize classification accuracy.

Table 1: Summary of Technology Stack

Layer / Module	Technologies	Purpose
Frontend UI	HTML5, CSS3, JS	User interface & dashboard
Mapping & GPS	Leaflet, OSM, GPS API	Live tracking & nearby search
Backend Server	Python, Flask	Routing, sessions & API
AI & ML	Scikit-learn, Random Forest	Risk & safety score prediction
Database	SQLite RDBMS	Profiles, contacts & history
Data Vis	Chart.js	Analytics & risk trends
Deployment	VS Code, Git, Render	Development & cloud hosting

7. RESULTS AND DISCUSSION

Results

The proposed Smart Women Safety System was evaluated through real-time testing of its safety monitoring, location tracking, AI prediction, and emergency response features. The application was deployed as a web-based platform and tested under different safety scenarios to evaluate its functionality and user experience. The experimental results demonstrate that the system successfully provides intelligent safety prediction, interactive location visualization, emergency assistance, and AI-driven recommendations.

DISCUSSION

The results demonstrate that the proposed Smart Women Safety System effectively enhances women's personal safety by integrating Artificial Intelligence with real-time location-based services. The implementation of AI-based safety prediction, live location tracking, emergency SOS, Voice SOS, and nearby emergency service identification provides users with timely assistance and proactive safety recommendations. The interactive dashboard, AI Safety Score, and safety analytics further improve user awareness by presenting safety information in a clear and organized manner.

The system reduces dependence on conventional emergency applications by offering predictive risk assessment instead of relying solely on reactive emergency responses. Features such as safe route recommendation, trusted contact management, and real-time location monitoring contribute to faster decision-making and improved emergency preparedness.

CONCLUSION

This paper presented the Smart Women Safety System, an intelligent web-based platform developed to enhance women's personal safety through the integration of Artificial Intelligence, Machine Learning, and location-based services. The system combines real-time location tracking, AI-based safety prediction, emergency assistance, and interactive mapping to provide users with proactive safety monitoring and timely support. It addresses major challenges associated with conventional safety applications, such as the lack of intelligent risk analysis, limited emergency features, and the absence of personalized safety recommendations.

The proposed solution enables users to monitor their surroundings through an AI Safety Score, identify nearby police stations and hospitals, receive safe route recommendations, and activate emergency assistance using SOS and Voice SOS features. Future work will focus on enhancing the intelligence and scalability of the system by integrating real-time crime databases, improving prediction accuracy using Deep Learning, developing dedicated mobile applications, and enabling direct connectivity with government emergency services.

ACKNOWLEDGEMENT

The authors express sincere gratitude to the Department of Computer Engineering, Suryodaya College of Engineering and Technology, Nagpur, and project guide Prof. Mrunali Gajbhiye for guidance and constant encouragement.
